

Statistics

Summary

- `ggplot()` specifies what data to use and what variables will be mapped to where
- inside `ggplot()`, `aes(x = , y = , color =)` specify what variables correspond to what aspects of the plot in general
- layers of plots can be combined using the `+` at the **end** of lines
- use `geom_line()` and `geom_point()` to add lines and points
- sometimes you need to add a `group` element to `aes()` if your plot looks strange
- make sure you are plotting what you think you are by checking the numbers!
- `facet_grid(~variable)` and `facet_wrap(~variable)` can be helpful to quickly split up your plot

Summary

- the factor class allows us to have a different order from alphanumeric for categorical data
- we can change data to be a factor variable using `mutate()`, `as_factor()` (in the `forcats` package), or `factor()` functions and specifying the levels with the `levels` argument
- `fct_reorder({variable_to_reorder}, {variable_to_order_by})` helps us reorder a variable by the values of another variable
- arranging, tabulating, and plotting the data will reflect the new order

Overview

We will cover how to use R to compute some of basic statistics and fit some basic statistical models.

- Correlation
- T-test
- Linear Regression / Logistic Regression

Overview

□ We will focus on how to use R software to do these. We will be glossing over the statistical **theory** and “formulas” for these tests. Moreover, we do not claim the data we use for demonstration meet **assumptions** of the methods. □

There are plenty of resources online for learning more about these methods, as well as dedicated Biostatistics series (at different advancement levels) at the JHU School of Public Health.

Check out www.opencasestudies.org for deeper dives on some of the concepts covered here and the [resource page](#) for more resources.

Correlation

Correlation

The correlation coefficient is a summary statistic that measures the strength of a linear relationship between two numeric variables.

- The strength of the relationship - based on how well the points form a line
- The direction of the relationship - based on if the points progress upward or downward

[source](#)

See this [case study](#) for more information.

Correlation

Function `cor()` computes correlation in R.

```
cor(x, y = NULL, use = c("everything", "complete.obs"),  
    method = c("pearson", "kendall", "spearman"))
```

- provide two numeric vectors of the same length (arguments `x`, `y`), or
- provide a `data.frame` / `tibble` with numeric columns only
- by default, Pearson correlation coefficient is computed

Correlation test

Function `cor.test()` also computes correlation and tests for association.

```
cor.test(x, y = NULL, alternative=c("two.sided", "less", "greater"),  
        method = c("pearson", "kendall", "spearman"))
```

- provide two numeric vectors of the same length (arguments `x`, `y`), or
- provide a `data.frame` / `tibble` with numeric columns only
- by default, Pearson correlation coefficient is computed
- alternative values:
 - `two.sided` means true correlation coefficient is not equal to zero (default)
 - `greater` means true correlation coefficient is > 0 (positive relationship)
 - `less` means true correlation coefficient is < 0 (negative relationship)

Correlation

```
circ <- read_csv("https://jhudatascience.org/intro_to_r/data/Charm_City_Circulat")
head(circ)
```

```
# A tibble: 6 × 15
```

	day <chr>	date <chr>	orangeBoardings <dbl>	orangeAlightings <dbl>	orangeAverage <dbl>	purpleBoardings <dbl>
1	Monday	01/1...	877	1027	952	NA
2	Tuesday	01/1...	777	815	796	NA
3	Wednesday	01/1...	1203	1220	1212.	NA
4	Thursday	01/1...	1194	1233	1214.	NA
5	Friday	01/1...	1645	1643	1644	NA
6	Saturday	01/1...	1457	1524	1490.	NA

```
# 9 more variables: purpleAlightings <dbl>, purpleAverage <dbl>,  
# greenBoardings <dbl>, greenAlightings <dbl>, greenAverage <dbl>,  
# bannerBoardings <dbl>, bannerAlightings <dbl>, bannerAverage <dbl>,  
# daily <dbl>
```

Correlation for two vectors

First, we compute correlation by providing two vectors.

Like other functions, if there are **NAs**, you get **NA** as the result. But if you specify use only the complete observations, then it will give you correlation using the non-missing data.

```
# x and y must be numeric vectors  
x <- circ %>% pull(orangeAverage)  
y <- circ %>% pull(purpleAverage)  
  
# have to specify which data on each axis  
# can accomodate missing data  
plot(x, y)
```

Correlation coefficient calculation and test

```
library(broom)  
cor(x, y)
```

```
[1] NA
```

```
cor(x, y, use = "complete.obs")
```

```
[1] 0.9195356
```

```
cor.test(x, y)
```

Pearson's product-moment correlation

data: x and y

t = 73.656, df = 991, p-value < 0.00000000000000000022

alternative hypothesis: true correlation is not equal to 0

95 percent confidence interval:

0.9093438 0.9286245

sample estimates:

cor

0.9195356

Broom package

The `broom` package helps make stats results look tidy

```
cor_result <- tidy(cor.test(x, y))  
glimpse(cor_result)
```

```
Rows: 1  
Columns: 8  
$ estimate    <dbl> 0.9195356  
$ statistic    <dbl> 73.65553  
$ p.value      <dbl> 0  
$ parameter    <int> 991  
$ conf.low     <dbl> 0.9093438  
$ conf.high    <dbl> 0.9286245  
$ method       <chr> "Pearson's product-moment correlation"  
$ alternative  <chr> "two.sided"
```

Correlation for two vectors with plot

In plot form... `geom_smooth()` and `annotate()` can help.

```
corr_value <- pull(cor_result, estimate) %>% round(digits = 4)
cor_label <- paste0("R = ", corr_value)
circ %>%
  ggplot(aes(x = orangeAverage, y = purpleAverage)) +
  geom_point(size = 0.3) +
  geom_smooth() +
  annotate("text", x = 2000, y = 7500, label = cor_label)
```

Correlation for data frame columns

We can compute correlation for all pairs of columns of a data frame / matrix.
This is often called, *“computing a correlation matrix”*.

Columns must be all numeric!

```
circ_subset_Average <- circ %>% select(ends_with("Average"))  
head(circ_subset_Average)
```

```
# A tibble: 6 × 4
```

	orangeAverage <dbl>	purpleAverage <dbl>	greenAverage <dbl>	bannerAverage <dbl>
1	952	NA	NA	NA
2	796	NA	NA	NA
3	1212.	NA	NA	NA
4	1214.	NA	NA	NA
5	1644	NA	NA	NA
6	1490.	NA	NA	NA

Correlation for data frame columns

We can compute correlation for all pairs of columns of a data frame / matrix. This is often called, *“computing a correlation matrix”*.

```
cor_mat <- cor(circ_subset_Average, use = "complete.obs")  
cor_mat
```

	orangeAverage	purpleAverage	greenAverage	bannerAverage
orangeAverage	1.0000000	0.9078826	0.8395806	0.5447031
purpleAverage	0.9078826	1.0000000	0.8665630	0.5213462
greenAverage	0.8395806	0.8665630	1.0000000	0.4533421
bannerAverage	0.5447031	0.5213462	0.4533421	1.0000000

Correlation for data frame columns with plot

corrplot package can make correlation matrix plots

```
library(corrplot)  
corrplot(cor_mat)
```

Correlation does not imply causation

Lyme disease incidence

Number of fried chicken restaurants (chain A)

[source](#)

T-test

T-test

The commonly used are:

- **one-sample t-test** – used to test mean of a variable in one group
- **two-sample t-test** – used to test difference in means of a variable between two groups (if the “two groups” are data of the *same* individuals collected at 2 time points, we say it is two-sample paired t-test)

The `t.test()` function in R is one to address the above.

```
t.test(x, y = NULL,  
       alternative = c("two.sided", "less", "greater"),  
       mu = 0, paired = FALSE, var.equal = FALSE,  
       conf.level = 0.95, ...)
```

Running one-sample t-test

It tests the mean of a variable in one group. By default (i.e., without us explicitly specifying values of other arguments):

- tests whether a mean of a variable is equal to 0 (`mu = 0`)
- uses “two sided” alternative (`alternative = "two.sided"`)
- returns result assuming confidence level 0.95 (`conf.level = 0.95`)
- omits **NA** values in data

```
x <- circ %>% pull(orangeAverage)
sum(is.na(x)) # count NAs in x
```

```
[1] 10
```

```
t.test(x)
```

One Sample t-test

```
data: x
t = 83.279, df = 1135, p-value < 0.000000000000000022
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
 2961.700 3104.622
sample estimates:
mean of x
 3033.161
```

Running two-sample t-test

It tests the difference in means of a variable between two groups. By default:

- tests whether difference in means of a variable is equal to 0 (`mu = 0`)
- uses “two sided” alternative (`alternative = "two.sided"`)
- returns result assuming confidence level 0.95 (`conf.level = 0.95`)
- assumes data are not paired (`paired = FALSE`)
- assumes true variance in the two groups is not equal (`var.equal = FALSE`)
- omits NA values in data

Check out this [case study](#) and this [case study](#) for more information.

Running two-sample t-test in R

```
x <- circ %>% pull(orangeAverage)
y <- circ %>% pull(purpleAverage)
sum(is.na(x))
```

```
[1] 10
```

```
sum(is.na(y)) # count NAs in x and y
```

```
[1] 153
```

```
t.test(x, y)
```

Welch Two Sample t-test

data: x and y

t = -17.076, df = 1984, p-value < 0.00000000000000000022

alternative hypothesis: true difference in means is not equal to 0

95 percent confidence interval:

-1096.7602 -870.7867

sample estimates:

mean of x mean of y

3033.161 4016.935

T-test: retrieving information from the result with **broom** package

The **broom** package has a `tidy()` function that can organize results into a data frame so that they are easily manipulated (or nicely printed)

```
result <- t.test(x, y)
result_tidy <- tidy(result)
glimpse(result_tidy)
```

```
Rows: 1  
Columns: 10  
$ estimate      <dbl> -983.7735  
$ estimate1     <dbl> 3033.161  
$ estimate2     <dbl> 4016.935  
$ statistic     <dbl> -17.07579  
$ p.value       <dbl> 0.0000000000000000000000000000000000000000000000000000000...  
$ parameter     <dbl> 1983.954  
$ conf.low      <dbl> -1096.76  
$ conf.high     <dbl> -870.7867  
$ method        <chr> "Welch Two Sample t-test"  
$ alternative    <chr> "two.sided"
```

P-value adjustment

▯ You run an increased risk of Type I errors (a “false positive”) when multiple hypotheses are tested simultaneously. ▯

Use the `p.adjust()` function on a vector of p values. Use `method =` to specify the adjustment method:

```
my_pvalues <- c(0.049, 0.001, 0.31, 0.00001)
p.adjust(my_pvalues, method = "BH") # Benjamini Hochberg
```

```
[1] 0.06533333 0.00200000 0.31000000 0.00004000
```

```
p.adjust(my_pvalues, method = "bonferroni") # multiply by number of tests
```

```
[1] 0.19600 0.00400 1.00000 0.00004
```

```
my_pvalues * 4
```

```
[1] 0.19600 0.00400 1.24000 0.00004
```

See [here](#) for more about multiple testing correction. Bonferroni also often done as p value threshold divided by number of tests (0.05/test number).

Some other statistical tests

- `wilcox.test()` – Wilcoxon signed rank test, Wilcoxon rank sum test
- `shapiro.test()` – Shapiro test
- `ks.test()` – Kolmogorov-Smirnov test
- `var.test()` – Fisher's F-Test
- `chisq.test()` – Chi-squared test
- `aov()` – Analysis of Variance (ANOVA)

Summary

- Use `cor()` to calculate correlation between two vectors, `cor.test()` can give more information.
- `corrplot()` is nice for a quick visualization!
- `t.test()` one sample test to test the difference in mean of a single vector from zero (one input)
- `t.test()` two sample test to test the difference in means between two vectors (two inputs)
- `tidy()` in the **broom** package is useful for organizing and saving statistical test output
- Remember to adjust p-values with `p.adjust()` when doing multiple tests on data

Lab Part 1

▮ [Class Website](#)

▮ [Lab](#)

Regression

Linear regression

Linear regression is a method to model the relationship between a response and one or more explanatory variables.

Most commonly used statistical tests are actually specialized regressions, including the two sample t-test, [see here for more](#).

Linear regression notation

Here is some of the notation, so it is easier to understand the commands/results.

$$y_i = \alpha + \beta x_i + \varepsilon_i$$

where:

- y_i is the outcome for person i
- α is the intercept
- β is the slope (also called a coefficient) - the mean change in y that we would expect for one unit change in x ("rise over run")
- x_i is the predictor for person i
- ε_i is the residual variation for person i

Linear regression

Linear regression

Linear regression is a method to model the relationship between a response and one or more explanatory variables.

We provide a little notation here so some of the commands are easier to put in the proper context.

$$y_i = \alpha + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i$$

where:

- y_i is the outcome for person i
- α is the intercept
- $\beta_1, \beta_2, \beta_3$ are the slopes/coefficients for variables x_{i1}, x_{i2}, x_{i3} - average difference in y for a unit change (or each value) in x while accounting for other variables
- x_{i1}, x_{i2}, x_{i3} are the predictors for person i
- ε_i is the residual variation for person i

See this [case study](#) for more details.

Linear regression fit in R

To fit regression models in R, we use the function `glm()` (Generalized Linear Model).

You may also see `lm()` which is a more limited function that only allows for normally/Gaussian distributed error terms (aka typical linear regressions).

We typically provide two arguments:

- `formula` – model formula written using names of columns in our data
- `data` – our data frame

Linear regression fit in R: model formula

Model formula

$$y_i = \alpha + \beta x_i + \varepsilon_i$$

In R translates to

$$y \sim x$$

Linear regression fit in R: model formula

Model formula

$$y_i = \alpha + \beta x_i + \varepsilon_i$$

In R translates to

$$y \sim x$$

In practice, y and x are replaced with the **names of columns from our data set**.

For example, if we want to fit a regression model where outcome is `income` and predictor is `years_of_education`, our formula would be:

```
income ~ years_of_education
```

Linear regression fit in R: model formula

Model formula

$$y_i = \alpha + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \varepsilon_i$$

In R translates to

$$y \sim x1 + x2 + x3$$

In practice, `y` and `x1`, `x2`, `x3` are replaced with the **names of columns from our data set**.

For example, if we want to fit a regression model where outcome is `income` and predictors are `years_of_education`, `age`, and `location` then our formula would be:

```
income ~ years_of_education + age + location
```

Linear regression

We will use data about emergency room doctor complaints.

“Data was recorded on 44 doctors working in an emergency service at a hospital to study the factors affecting the number of complaints received.”

```
# install.packages("faraway")  
library(faraway)
```

```
data(esdcomp)  
esdcomp
```

	visits	complaints	residency	gender	revenue	hours

Linear regression: model fitting

We fit linear regression model with the number of patient visits (**visits**) as an outcome and total number of hours worked (**hours**) as a predictor. In other words, we are evaluation if the number of hours worked is predictive of the number of visits a doctor had.

```
fit <- glm(visits ~ hours, data = esdcomp)
fit
```

```
Call:  glm(formula = visits ~ hours, data = esdcomp)
```

```
Coefficients:
```

(Intercept)	hours
140.288	1.584

```
Degrees of Freedom: 43 Total (i.e. Null); 42 Residual
```

```
Null Deviance: 16920000
```

```
Residual Deviance: 5383000 AIC: 646.3
```

Linear regression: model summary

The `summary()` function returns a list that shows us some more detail

```
summary(fit)
```

Call:

```
glm(formula = visits ~ hours, data = esdcomp)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	140.288	242.723	0.578	0.566
hours	1.584	0.167	9.488	0.000000000000526 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for gaussian family taken to be 128155.3)

Null deviance: 16919101 on 43 degrees of freedom

Residual deviance: 5382524 on 42 degrees of freedom

AIC: 646.3

Number of Fisher Scoring iterations: 2

tidy results

The broom package can help us here too! The estimate is the coefficient or slope - for one change in hours worked (1 hour increase), we see 1.58 more visits. The error for this estimate is relatively small at 0.167. This relationship appears to be significant with a small p value <0.001 .

```
tidy(fit) %>% glimpse()
```

```
Rows: 2
```

```
Columns: 5
```

```
$ term      <chr> "(Intercept)", "hours"
```

```
$ estimate  <dbl> 140.28841, 1.58408
```

```
$ std.error <dbl> 242.7225866, 0.1669579
```

```
$ statistic <dbl> 0.5779784, 9.4879004
```

```
$ p.value   <dbl> 0.566364879085634154, 0.0000000000005262224
```

Linear regression: multiple predictors

Let's try adding another explanatory variable to our model, dollars per hour earned by the doctor (**revenue**). The tidy function will not work with this unfortunately. The meaning of coefficients is more complicated here.

```
fit2 <- glm(visits ~ hours + revenue, data = esdcomp)
summary(fit2)
```

Call:

```
glm(formula = visits ~ hours + revenue, data = esdcomp)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)	
(Intercept)	-2078.1369	327.9157	-6.337	0.00000014326	***
hours	1.6179	0.1081	14.968	< 0.00000000000000002	***
revenue	8.3437	1.0828	7.706	0.00000000169	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for gaussian family taken to be 53620.97)

Null deviance: 16919101 on 43 degrees of freedom

Residual deviance: 2198460 on 41 degrees of freedom

AIC: 608.91

Number of Fisher Scoring iterations: 2

Linear regression: multiple predictors

Can also use `tidy` and `glimpse` to see the output nicely.

```
fit2 <- glm(visits ~ hours + revenue, data = esdcomp)
fit2 %>%
  tidy() %>%
  glimpse()
```

Rows: 3

Columns: 5

```
$ term      <chr> "(Intercept)", "hours", "revenue"
$ estimate  <dbl> -2078.136879, 1.617854, 8.343689
$ std.error <dbl> 327.9156731, 0.1080845, 1.0827657
$ statistic <dbl> -6.337412, 14.968422, 7.705904
$ p.value   <dbl> 0.00000014326245193176067, 0.0000000000000000000324554, 0.0000...
```

Linear regression: factors

Factors get special treatment in regression models - lowest level of the factor is the comparison group, and all other factors are **relative** to its values.

`residency` takes values Y or N to indicate whether the doctor is a resident.

```
esdcomp %>% count(residency)
```

	residency	n
1	N	24
2	Y	20

Linear regression: factors

Yes relative to No - baseline is no

```
fit_3 <- glm(visits ~ residency, data = esdcomp)
summary(fit_3)
```

Call:

```
glm(formula = visits ~ residency, data = esdcomp)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	2510.8	126.3	19.87	<0.00000000000000002 ***
residencyY	-275.5	187.4	-1.47	0.149

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for gaussian family taken to be 383122.6)

Null deviance: 16919101 on 43 degrees of freedom

Residual deviance: 16091148 on 42 degrees of freedom

AIC: 694.49

Number of Fisher Scoring iterations: 2

Linear regression: factors

Comparison group is not listed - treated as intercept. All other estimates are relative to the intercept.

```
circ <- read_csv("https://jhudatascience.org/intro_to_r/data/Charm_City_Circulator_Ridership.csv")
fit_4 <- glm(orangeBoardings ~ factor(day), data = circ)
summary(fit_4)
```

```
Call:
glm(formula = orangeBoardings ~ factor(day), data = circ)
```

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)

(Dispersion parameter for gaussian family taken to be 1238057)

Null deviance: 11540692004 on 1079 degrees of freedom

Residual deviance: 1327197363 on 1072 degrees of freedom

(67 observations deleted due to missingness)

AIC: 18208

Number of Fisher Scoring iterations: 2

Linear regression: interactions

Can also specify interactions between variables in a formula $y \sim x1 + x2 + x1 * x2$. This allows for not only the intercepts between factors to differ, but also the slopes with regard to the interacting variable.

```
fit_7 <- glm(visits ~ hours + residency + hours * residency, data = esdcomp)
tidy(fit_7)
```

```
# A tibble: 4 × 5
```

	term <chr>	estimate <dbl>	std.error <dbl>	statistic <dbl>	p.value <dbl>
1	(Intercept)	469.	481.	0.976	0.335
2	hours	1.32	0.308	4.30	0.000108
3	residencyY	-642.	559.	-1.15	0.258
4	hours:residencyY	0.574	0.377	1.52	0.136

Linear regression: interactions

By default, `ggplot` with a factor added as a color will look include the interaction term. Notice the different intercept and slope of the lines.

```
ggplot(esdcomp, aes(x = hours, y = visits, color = residency)) +  
  geom_point(size = 1, alpha = 0.8) +  
  geom_smooth(method = "glm", se = FALSE) +  
  scale_color_manual(values = c("black", "grey50")) +  
  theme_classic()
```

Generalized linear models (GLMs)

Generalized linear models (GLMs) allow for fitting regressions for non-continuous/normal outcomes. Examples include: logistic regression, Poisson regression.

Add the `family` argument – a description of the error distribution and link function to be used in the model. These include:

- `binomial(link = "logit")` - outcome is binary
- `poisson(link = "log")` - outcome is count or rate
- others

Very important to use the right test!

See this [case study](#) for more information.

See `?family` documentation for details of family functions.

Logistic regression

We will use data about breast cancer tumors.

“The purpose of this study was to determine whether a new procedure called fine needle aspiration which draws only a small sample of tissue could be effective in determining tumor status.”

```
data(wbca)
wbca
```

	Class	Adhes	BNucl	Chrom	Epith	Mitos	NNucl	Thick	UShap	USize

Logistic regression

Class is a 0/1-valued variable indicating if the tumor was malignant (0 if malignant, 1 if benign).

```
# General format
```

```
glm(y ~ x, data = DATASET_NAME, family = binomial(link = "logit"))
```

```
binom_fit <- glm(Class ~ UShap + USize, data = wbca, family = binomial(link = "logit"))
summary(binom_fit)
```

Call:

```
glm(formula = Class ~ UShap + USize, family = binomial(link = "logit"),
    data = wbca)
```

Coefficients:

	Estimate	Std. Error	z value	Pr(> z)	
(Intercept)	5.6868	0.4359	13.047	< 0.00000000000000002	***

USize	-0.8686	0.1690	-5.139	0.000000277	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for binomial family taken to be 1)

Null deviance: 881.39 on 680 degrees of freedom

Residual deviance: 218.28 on 678 degrees of freedom

AIC: 224.28

Number of Fisher Scoring iterations: 7

Odds ratios

An odds ratio (OR) is a measure of association between an exposure and an outcome. The OR represents the odds that an outcome will occur given a particular exposure, compared to the odds of the outcome occurring in the absence of that exposure.

Check out [this paper](#).

Odds ratios

This data shows whether people became ill after eating ice cream in the 1940s.

```
# install.packages(epitools)
library(epitools)
data(oswego)
ice_cream <-
  oswego %>%
  select(ill, vanilla.ice.cream) %>%
  mutate(
    ill = recode(ill, "Y" = 1, "N" = 0),
    vanilla.ice.cream = recode(vanilla.ice.cream, "Y" = 1, "N" = 0)
  )
```

Odds ratios

```
head(ice_cream)
```

```
  ill vanilla.ice.cream
1    1                  1
2    1                  1
3    1                  1
4    1                  1
5    1                  1
6    1                  1
```

```
ice_cream %>% count(ill, vanilla.ice.cream)
```

```
  ill vanilla.ice.cream  n
1    0                  0 18
2    0                  1 11
3    1                  0  3
4    1                  1 43
```

Odds ratios

Use `oddsratio(x, y)` from the `epitools()` package to calculate odds ratios.

```
library(epitools)
response <- ice_cream %>% pull(ill)
predictor <- ice_cream %>% pull(vanilla.ice.cream)
oddsratio(predictor, response)
```

See this [case study](#) for more information.

Final note

Some final notes:

- Researcher's responsibility to **understand the statistical method** they use – underlying assumptions, correct interpretation of method results
- Researcher's responsibility to **understand the R software** they use – meaning of function's arguments and meaning of function's output elements

Summary

- `glm()` fits regression models:
 - Use the `formula` = argument to specify the model (e.g., $y \sim x$ or $y \sim x1 + x2$ using column names)
 - Use `data` = to indicate the dataset
 - Use `family` = to do a other regressions like logistic, Poisson and more
 - `summary()` gives useful statistics
- `oddsratio()` from the `epitools` package can calculate odds ratios (outside of logistic regression - which allows more than one explanatory variable)
- this is just the tip of the iceberg!
