Manipulating Data in R

Recap of Data Cleaning

- is.na(),any(is.na()), all(is.na()),count(), and functions from naniar like gg_miss_var() and miss_var_summary can help determine if we have NA values
- miss_var_which() can help you drop columns that have any missing values.
- filter() automatically removes NA values
- drop_na() can help you remove NA values
- NA values can change your calculation results
- think about what NA values represent don't drop them if you shouldn't
- replace_na() will replace `NA values with a particular value

Recap of Data Cleaning

- case_when() can recode entire values based on conditions
 - remember case_when() needs TRUE ~ variable to keep values that aren't specified by conditions, otherwise will be NA
- stringr package has great functions for looking for specific parts of values especially filter() and str_detect() combined
 - also has other useful string manipulation functions like str_replace()
 and more!
 - separate() can split columns into additional columns
 - unite() can combine columns

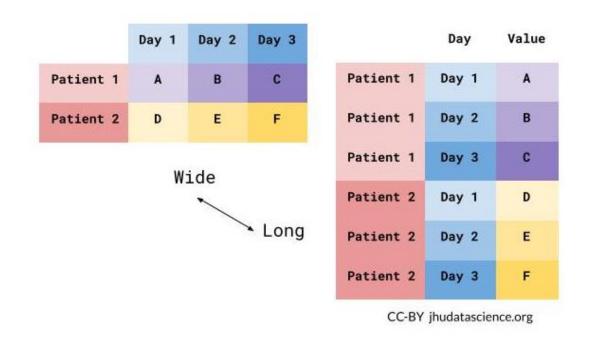

Day 5 Cheatsheet

Manipulating Data

In this module, we will show you how to:

- 1. Reshape data from wide to long
- 2. Reshape data from long to wide
- 3. Merge Data/Joins

Data is wide or long with respect to certain variables.

Data is stored *differently* in the tibble.

Here's a small dataset looking at vaccination rates over three months in Alabama.

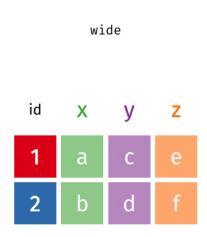

Wide: has many columns

Long: column names become data

Wide: multiple columns per individual, values spread across multiple columns

Long: multiple rows per observation, a single column contains the values

https://github.com/gadenbuie/tidyexplain/blob/main/images/tidyr-pivoting.gif

Why do we need to switch between wide/long data?

Wide: Easier for humans to read

Long: Easier for R to make plots & do analysis

Pivoting using tidyr package (part of tidyverse)

tidyr allows you to "tidy" your data. We will be talking about:

- pivot_longer make multiple columns into variables, (wide to long)
- pivot_wider make a variable into multiple columns, (long to wide)

The reshape command exists. Its arguments are considered more confusing, so we don't recommend it.

You might see old functions gather and spread when googling. These are older iterations of pivot_longer and pivot_wider, respectively.

pivot_longer...

Reshaping data from wide to long

ex wide # A tibble: 2×4 June_vacc_rate May_vacc_rate April_vacc_rate State <chr> <fdb>> <dbl> <fdb>> 1 Alabama 0.516 0.5140.511 2 Alaska 0.627 0.626 0.623 ex_long <- ex_wide %>% pivot_longer(cols = ends_with("rate")) ex long # A tibble: 6×3 State value name <chr> <chr> <dbl> 1 Alabama June vacc rate 0.516 2 Alabama May vacc rate 0.514 3 Alabama April_vacc_rate 0.511 4 Alaska June vacc rate 0.627 5 Alaska May_vacc_rate 0.626 6 Alaska April vacc rate 0.623

GUT CHECK!

What does pivot_longer() do?

- A. Summarize data
- B. Import data
- C. Reshape data

Reshaping wide to long: Better column names

pivot_longer() - puts column data into rows (tidyr package)

- First describe which columns we want to "pivot_longer"
- names_to = new name for old columns
- values_to = new name for old cell values

Reshaping wide to long: Better column names

Newly created column names ("Month" and "Rate") are enclosed in quotation marks. It helps us be more specific than "name" and "value".

```
ex_long <- ex_wide %>% pivot_longer(cols = ends_with("rate"),
                                    names to = "Month",
                                    values to = "Rate")
ex long
# A tibble: 6 × 3
  State
         Month
                          Rate
  <chr>
          <chr>
                          <dbl>
1 Alabama June_vacc_rate 0.516
2 Alabama May_vacc_rate
                          0.514
3 Alabama April_vacc_rate 0.511
4 Alaska June_vacc_rate 0.627
5 Alaska May_vacc_rate
                         0.626
6 Alaska April_vacc_rate 0.623
```

Data used: Charm City Circulator

```
circ <-
  read_csv("http://jhudatascience.org/intro_to_r/data/Charm_City_Circulator_Ridership.csv")

    bannerBoardings <dbl>, bannerAlightings <dbl>, bannerAverage <dbl>,
#
    daily <dbl>
#
```

Mission: Taking the average boardings by line

Let's imagine we want to create a table of average boardings by route/line. Results should look something like:

Reshaping data from wide to long

```
long <- circ %>%
  pivot_longer(starts_with(c("orange", "purple", "green", "banner")))
long
# A tibble: 13,752 × 5
         date daily name
                                            value
   dav
   <chr> <chr> <dbl> <chr>
                                            <dbl>
                       952 orangeBoardings
                                              877
 1 Monday 01/11/2010
 2 Monday 01/11/2010
                       952 orangeAlightings
                                             1027
 3 Monday 01/11/2010
                       952 orangeAverage
                                              952
                       952 purpleBoardings
 4 Monday 01/11/2010
                                               NA
 5 Monday 01/11/2010
                       952 purpleAlightings
                                               NA
                       952 purpleAverage
 6 Monday 01/11/2010
                                               NA
 7 Monday 01/11/2010
                       952 greenBoardings
                                               NA
 8 Monday 01/11/2010
                       952 greenAlightings
                                               NA
 9 Monday 01/11/2010
                       952 greenAverage
                                               NA
10 Monday 01/11/2010
                       952 bannerBoardings
                                               NA
# 13,742 more rows
```

Just keep "boardings"

Filter by Boardings only..

```
long <- long %>% filter(str_detect(name, "Boardings"))
long
# A tibble: 4 584 x 5
```

```
# A tibble: 4,584 × 5
  day
            date
                       daily name
                                            value
            <chr>
                       <dbl> <chr>
                                             <dbl>
   <chr>
            01/11/2010
 1 Monday
                        952 orangeBoardings
                                              877

                             bannerBoardings
                                               NA
 9 Wednesday 01/13/2010 1212. orangeBoardings
                                              1203
10 Wednesday 01/13/2010 1212. purpleBoardings
                                                NA
# 0 4,574 more rows
```

Mission: Taking the average boardings by line

Now our data is more tidy, and we can take the averages easily!

```
long %>%
  group_by(name) %>%
  summarize("avg_boardings" = mean(value, na.rm = TRUE))
# A tibble: 4 \times 2
                  avg_boardings
  name
  <chr>
                          <dbl>
1 bannerBoardings
                          830.
2 greenBoardings
                          1929.
3 orangeBoardings
                        3031.
4 purpleBoardings
                       4127.
```

Reshaping data from wide to long

There are many ways to **select** the columns we want. Check out https://dplyr.tidyverse.org/reference/dplyr_tidy_select.html to look at more column selection options.

```
circ %>%
  pivot_longer( !c(day, date, daily))
# A tibble: 13,752 × 5
   day
         date
                    daily name
                                            value
   <chr> <chr>
                   <dbl> <chr>

# 13,742 more rows
```

pivot_wider...

Reshaping data from long to wide

pivot_wider() - spreads row data into columns (tidyr package)

- names_from = the old column whose contents will be spread into multiple new column names.
- values_from = the old column whose contents will fill in the values of those new columns.

Reshaping data from long to wide

We can use pivot_wider to convert long data to wide format. Let's try it with the vaccine data from earlier.

ex_long

Reshaping data from long to wide

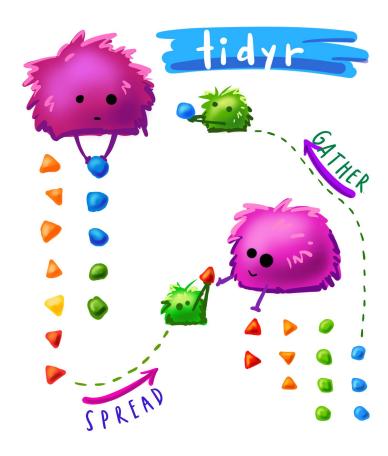

We can use pivot_wider to convert long data to wide format. Let's try it with the vaccine data from earlier.

```
ex_wide2 <- ex_long %>% pivot_wider(names_from = "Month",
                                     values_from = "Rate")
ex wide2
# A tibble: 2 \times 4
         June_vacc_rate May_vacc_rate April_vacc_rate
 State
 <chr>
                  <dbl>
                               <dbl>
                                              <dbl>
1 Alabama
                 0.516
                           0.514
                                              0.511
2 Alaska
                               0.626
                 0.627
                                              0.623
```

Reshaping Charm City Circulator

```
wide <- long %>% pivot_wider(names_from = "name",
                            values_from = "value")
wide

Summary

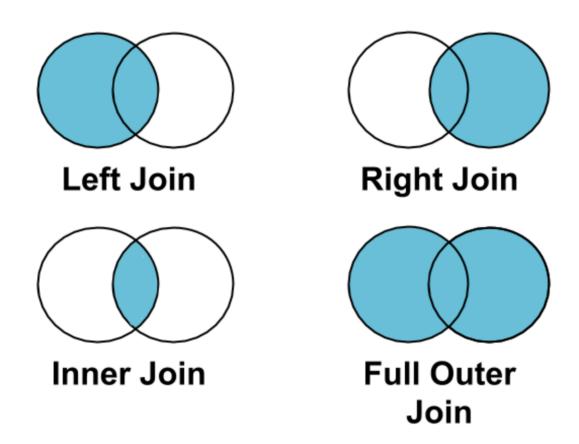

- tidyr package (part of tidyverse) helps us convert between wide and long data
- pivot_longer() goes from wide -> long
 - Specify columns you want to pivot
 - Specify names_to = and values_to = for custom naming
- pivot_wider() goes from long -> wide
 - Specify names_from = and values_from =

Lab Part 1

Joining

"Combining datasets"

Joining in dplyr

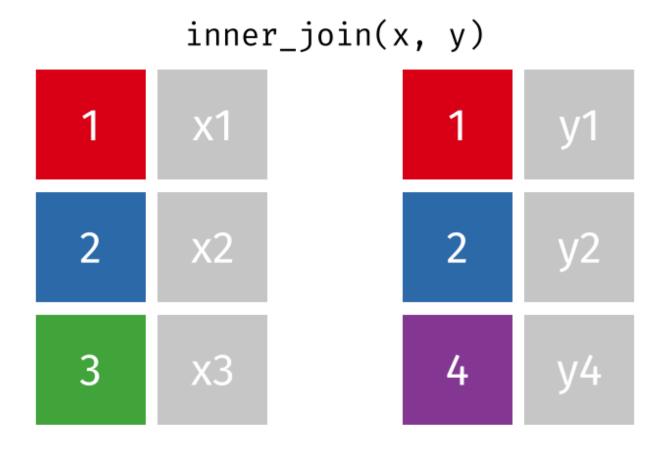

- Merging/joining data sets together usually on key variables, usually "id"
- · ?join see different types of joining for dplyr
- inner_join(x, y) only rows that match for x and y are kept
- full_join(x, y) all rows of x and y are kept
- left_join(x, y) all rows of x are kept even if not merged with y
- right_join(x, y) all rows of y are kept even if not merged with x
- anti_join(x, y) all rows from x not in y keeping just columns from x.

Merging: Simple Data

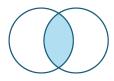

```
data As <- read csv(
  file = "https://jhudatascience.org/intro_to_r/data/data_As_1.csv")
data_cold <- read_csv(</pre>
  file = "https://jhudatascience.org/intro_to_r/data/data_cold_1.csv")
data As
# A tibble: 2 \times 3
 State June_vacc_rate May_vacc_rate
                  <dbl> <dbl>
 <chr>
1 Alabama
               0.516 0.514
2 Alaska
                 0.627
                               0.626
data cold
# A tibble: 2 \times 2
 State April_vacc_rate
 <chr>
                  <dbl>
1 Maine
                  0.795
2 Alaska
                  0.623
```

Inner Join

https://github.com/gadenbuie/tidyexplain/blob/main/images/inner-join.gif

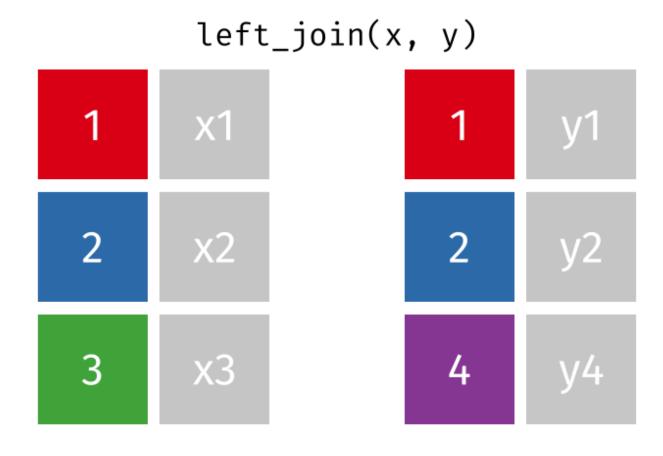

Inner Join

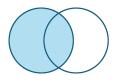

Left Join

https://raw.githubusercontent.com/gadenbuie/tidyexplain/main/images/left-join.gif

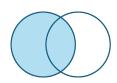

Left Join

```
"Everything to the left of the comma"
lj <- left_join(data_As, data_cold)</pre>
Joining with `by = join_by(State)`
1j
# A tibble: 2 \times 4
  State
          June_vacc_rate May_vacc_rate April_vacc_rate
  <chr>
                    <dbl>
                                  <dbl>
                                                   <dbl>
1 Alabama
                   0.516
                                  0.514
                                                  NA
2 Alaska
                   0.627
                                  0.626
                                                   0.623
```

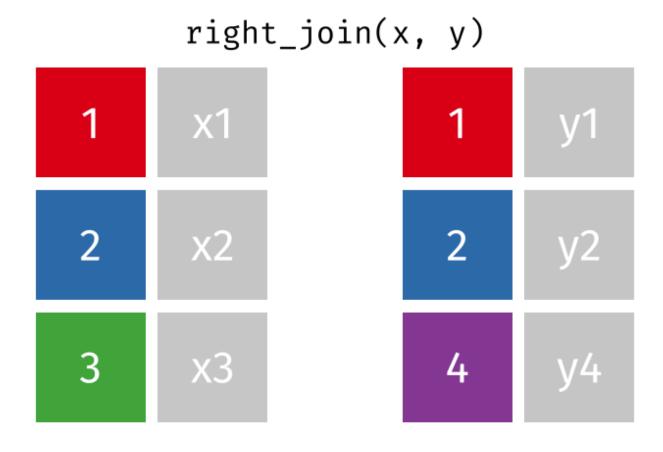

Install tidylog package to log outputs

```
# install.packages("tidylog")
library(tidylog)
left_join(data_As, data_cold)
Joining with `by = join_by(State)`
left_join: added one column (April_vacc_rate)
> rows only in data_As 1
> rows only in data_cold (1)
> matched rows 1
> ===
> rows total 2
# A tibble: 2 \times 4
 State
         June_vacc_rate May_vacc_rate April_vacc_rate
 <chr>
                <dbl> <dbl>
                                            <dbl>
1 Alabama
              0.516 0.514
                                           NA
2 Alaska
             0.627
                             0.626
                                           0.623
```

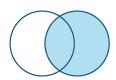

Right Join

https://raw.githubusercontent.com/gadenbuie/tidyexplain/main/images/right-join.gif

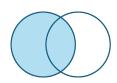

Right Join

```
"Everything to the right of the comma"
rj <- right_join(data_As, data_cold)</pre>
Joining with `by = join_by(State)`
right_join: added one column (April_vacc_rate)
> rows only in data_As (1)
> rows only in data_cold 1
> matched rows 1
> ===
> rows total 2
rj
# A tibble: 2 \times 4
  State June_vacc_rate May_vacc_rate April_vacc_rate
                        <dbl>
  <chr>
                 <dbl>
                                                <dbl>
1 Alaska
               0.627 0.626
                                               0.623
2 Maine
                                                0.795
                NA
                              NA
```

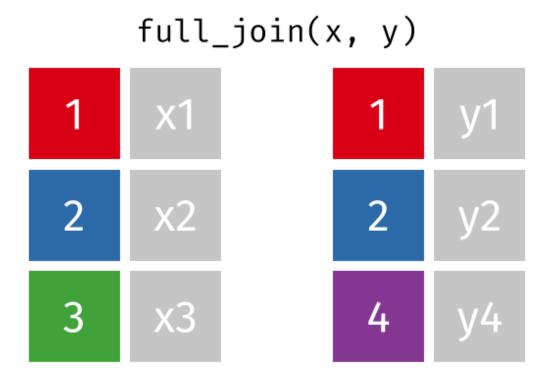

Left Join: Switching arguments

```
lj2 <- left_join(data_cold, data_As)</pre>
Joining with `by = join_by(State)`
left_join: added 2 columns (June_vacc_rate, May_vacc_rate)
> rows only in data_cold 1
> rows only in data_As (1)
> matched rows 1
> ===
> rows total 2
lj2
# A tibble: 2 \times 4
 State April_vacc_rate June_vacc_rate May_vacc_rate
                               <dbl>
 <chr>
                 <dbl>
                                           <dbl>
1 Maine
             0.795 NA
                                           NA
2 Alaska 0.623
                             0.627
                                           0.626
```

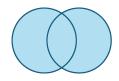

Full Join

https://raw.githubusercontent.com/gadenbuie/tidyexplain/main/images/full-join.gif

Full Join

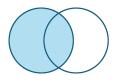

```
fj <- full_join(data_As, data_cold)</pre>
Joining with `by = join_by(State)`
full_join: added one column (April_vacc_rate)
> rows only in data_As 1
> rows only in data_cold 1
> matched rows 1
> ===
> rows total 3
fj
# A tibble: 3 \times 4
 State
         June_vacc_rate May_vacc_rate April_vacc_rate
 <chr>
                  <dbl>
                                <dbl>
                                               <dbl>
1 Alabama
                0.516 0.514
                                              NA
2 Alaska
               0.627
                              0.626
                                              0.623
3 Maine
                                               0.795
                 NA
                               NA
```

```
data_As <- read_csv(</pre>
  file = "https://jhudatascience.org/intro_to_r/data/data_As_2.csv")
data cold <- read csv(
  file = "https://jhudatascience.org/intro_to_r/data/data_cold_2.csv")
data As
# A tibble: 2 \times 2
  State state bird
  <chr> <chr>
1 Alabama wild turkey
2 Alaska willow ptarmigan
data_cold
# A tibble: 3 \times 3
  State vacc rate month
  <chr> <dbl> <chr>
1 Maine 0.795 April
2 Alaska 0.623 April
3 Alaska 0.626 May
```

```
lj <- left_join(data_As, data_cold)

Joining with `by = join_by(State)`
left_join: added 2 columns (vacc_rate, month)
> rows only in data_As 1
> rows only in data_cold (1)
> matched rows 2 (includes duplicates)
> ===
> rows total 3
```

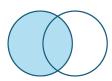

Data including the joining column ("State") has been duplicated.

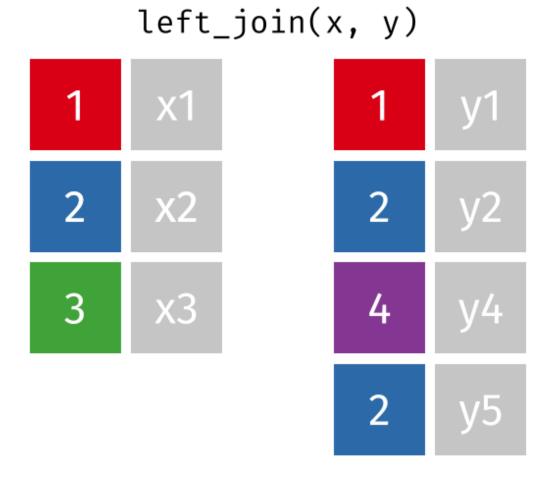

1j

```
# A tibble: 3 × 4
State state_bird vacc_rate month
<chr> <chr> <chr> 1 Alabama wild turkey NA <NA>
2 Alaska willow ptarmigan 0.623 April
3 Alaska willow ptarmigan 0.626 May
```

Note that "Alaska willow ptarmigan" appears twice.

https://github.com/gadenbuie/tidyexplain/blob/main/images/left-join-extra.gif

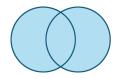

Stop tidylog

```
unloadNamespace() does the opposite of library().
unloadNamespace("tidylog")
```

Using the by argument

By default joins use the intersection of column names. If by is specified, it uses that.

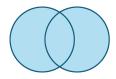

Using the by argument

You can join based on multiple columns by using something like by = c(col1, col2).

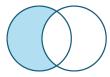

If the datasets have two different names for the same data, use:

$$full_join(x, y, by = c("a" = "b"))$$

anti_join: what's missing

```
Entries in data_As but not in data_cold
anti_join(data_As, data_cold, by = "State")
# A tibble: 1 \times 2
  State state bird
  <chr> <chr>
1 Alabama wild turkey
Entries in data_cold but not in data_As
anti_join(data_cold, data_As, by = "State") # order switched
# A tibble: 1 \times 3
  State vacc rate month
  <chr> <dbl> <chr>
1 Maine 0.795 April
```

GUT CHECK!

Why use join functions?

- A. Combine different data sources
- B. Connect Rmd to other files
- C. Using one data source is too easy and we want our analysis ~ fancy ~

Summary

- · Merging/joining data sets together assumes all column names that overlap
 - use the by = c("a" = "b") if they differ
- inner_join(x, y) only rows that match for x and y are kept
- full_join(x, y) all rows of x and y are kept
- left_join(x, y) all rows of x are kept even if not merged with y
- right_join(x, y) all rows of y are kept even if not merged with x
- Use the tidylog package for a detailed summary
- anti_join(x, y) shows what is only in x (missing from y)

Additional Slides

Getting the set difference with setdiff

We might want to determine what indexes ARE in the first dataset that AREN'T in the second.

For this to work, the datasets need the same columns.

We'll just select the index using select().

A_states <- data_As %>% select(State)
cold_states <- data_cold %>% select(State)

Getting the set difference with setdiff

```
States in A_states but not in cold_states
dplyr::setdiff(A_states, cold_states)
# A tibble: 1 \times 1
  State
  <chr>
1 Alabama
States in cold_states but not in A_states
dplyr::setdiff(cold_states, A_states)
# A tibble: 1 \times 1
  State
  <chr>
1 Maine
```

Getting the set difference with setdiff

Why did we use dplyr::setdiff?

There is a base R function, also called **setdiff** that requires vectors.

In other words, we use dplyr:: to be specific about the package we want to use.

More set operations can be found here: https://dplyr.tidyverse.org/reference/setops.html

Fast manipulation using collapse package

https://sebkrantz.github.io/collapse/

Might be helpful if your data is very large. However, dplyr and tidyr functions are great for most applications.
